LAMBPLAN Indexes

What they are and how to use them?

Dr Robert Banks - National Co-ordinator LAMBPLAN

LAMBPLAN - EBV's and Selection Indexes

LAMBPLAN provides sheep breeders with Estimated Breeding Values (EBV's) and Selection Indexes covering the entire range of sheep breeds and roles, and commercially important traits.

EBV's are simply pictures of animal's genes, expressed in units of production and are an estimate of the genetic merit of an animal for a particular trait. They are called BREEDING VALUES because they are the best guide to what will happen if a particular animal is used for breeding.

EBV's are based on objective measures of performance. For terminal sire breeds, growth rate, eye muscle depth and fat depth are objectively measured. These measurements are taken by the breeder and an accredited LAMBPLAN operator.

LAMBPLAN takes account of non-genetic factors known to affect the performance of lambs:

- whether born as a single, twin or triplet.
- whether reared as a single, twin or triplet.
- age (in days) at measurement.
- age of dam.

The adjustment factors used to correct for birth, rearing, age of lamb and age of dam in LAMBPLAN are calculated from the data itself. This means that each group of animals is treated as fairly as possible. It also means that adjustment factors vary between breeds and are the most accurate possible reflection of the actual effect of the various non-genetic factors on animal's performance.

LAMBPLAN then calculates the difference between each animal's adjusted record and the average of the management group. This difference is multiplied by the heritability of the trait to give the EBV.

The hereditary is the proportion of the observed difference that is due to genes, and can be passed on to progeny.

As well as the animal's own record for a particular trait, other information can be used to tell about its genes. Relatives (progeny, sire and dam, half brothers and sisters etc) share some of their genes so we can use measurements on these animals in producing EBV's. Using more information in this way makes the EBV a better guide to the value of the genes of each animal.

When two traits are affected to some extent by the same genes (genetically correlated), LAMBPLAN uses the animal's records for both traits when calculating the EBV for each trait. For example, there is a small genetic correlation between growth rate and leanness in meat sheep. By using an animal's measured fat depth together with its growth rate, you get a better picture of its genes for growth rate than by using growth rate alone.

LAMBPLAN uses both correlated traits and information from relatives in producing EBV's - LAMBPLAN uses all available information about each animal and its relatives to produce EBV's that are the best possible guide to the value of each animal's genes.

EBV's describe genetic merit in the units of each trait. For example, the EBV of an animal for weight is expressed in kilograms (kg). A ram with an EBV for weight of +1.0 has genes that are worth 1kg more than those of the average. Similarly for leanness, EBV's are expressed in terms of millimetres of fat (mm).

DISCLAIMER

"LAMBPLAN EBV's are calculated from raw data collected by breeders and accredited LAMBPLAN operators. LAMBPLAN does not oversee or audit the collection of this data and therefore neither LAMBPLAN nor the Meat Research Corporation accept any responsibility for the accuracy of the data.

LAMBPLAN EBV's are designed to give the best possible estimate of true genetic merit from that data, ie, the estimate that maximises the correlation between EBV's and true genetic merit. EBV's can only be compared between flocks or between management groups within a flock when a pedigree link exists and that link is used."
